# Progress report on thesis research: wind energy

Reporter: Zhang Jiarong

Tutor: Wang Yongwei

Date: 2017.1.5

# Outline

1. Research Significance
2. Present Research
3. Methodology
4. Technical route
5. Result and Discussion
6. Conclusion

# Research Significance

Wind energy resources in various region depend on local **density of wind energy** and **annual cumulative hours of available wind energy**, and wind energy resources are greatly affected by **topography**. Wind energy resources are abundant in china. Such as the southeast coast and its islands, Inner Mongolia and Northern Gansu, are the major wind energy resources in china.

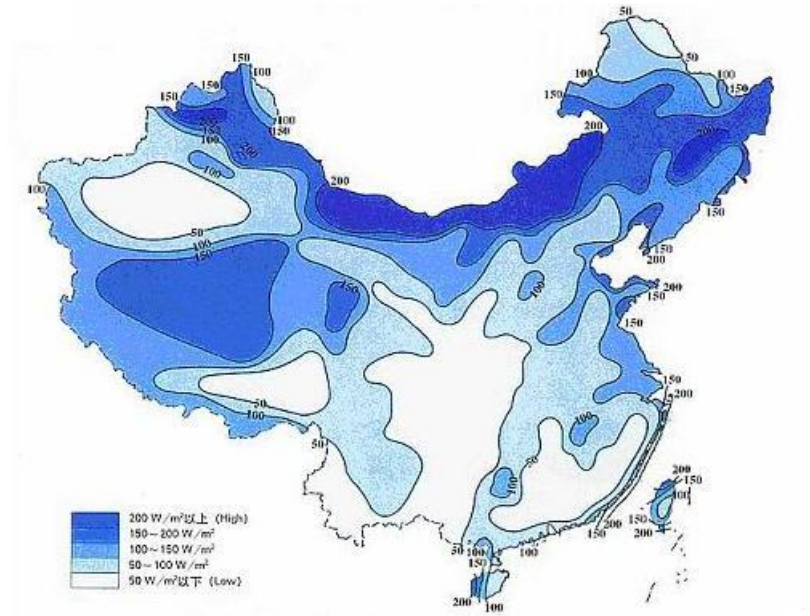

Fig 1 The wind energy resource distribution map

For the continuous expansion of wind power plants, **the wind energy resource assessment** and wind power forecasting, are becoming more and more important .

# Present Research

Wind resource assessment and wind power forecasting are targeted to the very **small scale**, which is a specific wind farm or a wind turbine. Wind farm scale is about a few square kilometers, the turbine is at 100 m level. And most of wind farms are in **complex terrain** conditions in remote areas. The atmospheric motion on the wind farm is impacted not only by **the regional atmospheric circulation**, but also by **local small-scale environment**. And a single meso-scale meteorological model or computational fluid dynamics model cannot meet the requirements of wind energy development.

In this paper, two advanced numerical simulation tools, meso-scale atmospheric model (**WRF**) and computational fluid dynamics model (**Fluent**), are combined to assess wind energy resources finely.

# Methodology

The Poyang Lake area in China is Wind energy seasonal utilization area, and wind energy resources are abundant in winter. The numerical simulation of **wind field** in Poyang Lake area is made by taking **a gale process** in 2010 in the winter of December as an example.

- Using WRF model to simulate the meteorological field in Poyang Lake area from **13 to 16 , December, 2010**.
- Based on the boundary conditions provided by the WRF simulation results, the numerical simulation of **wind field and turbulent flow field** near the jishan site ( $1.8\text{km} \times 1.8\text{km}$ ) and zaohu site ( $3.6\text{km} \times 3.6\text{km}$ ) is performed by using Fluent.

# Conclusion

- The advantage of the CFD model (Fluent) is that it can reflect the influence of many **small-scale topographic effects** on wind speed, is to simulate the **separation and rotation** of the flow after terrain, is to simulate **the turbulent scale of atmospheric movement**, it is the output of the wind speed change range greater than WRF, the rate of change (frequency) faster than WRF. The advantage of WRF in the **mean motion of the mesoscale atmospheric** simulation. Using a single site and hourly average simulation results to compare WRF and CFD, and can not be a good display of the advantages of CFD model.
- This method (WRF+Fluent) is a **one-way coupling**, WRF driven Fluent, WRF prediction is the basis of Fluent forecast. When the WRF prediction error is large, Fluent can not be completely corrected.

- It can be seen from the analysis of Figure 6 that the simulation results of WRF coupling Fluent to **high speed process** are good, which is significant for the development of wind energy resources.
- Although the WRF coupling Fluent and WRF direct output of the simulated wind speed is roughly the same, However, Fluent can give the **fine scale wind field information** as shown in Figure 12, which WRF cannot do.

Thank you
